msae: An R Package of Multivariate Fay Herriot Models for Small Area Estimation
by Novia Permatasari and Azka Ubaidillah

Abstract. The paper introduces an R Package of multivariate Fay-Herriot models for small area estimation named msa. This package implements four types of Fay-Herriot models, including univariate Fay-Herriot model (model 0), multivariate Fay-Herriot model (model 1), autoregressive multivariate Fay-Herriot model (model 2), and heteroskedastic autoregressive multivariate Fay-Herriot model (model 3). It also contains some datasets generated based on multivariate Fay-Herriot models. We describe and implement functions through various practical examples. Multivariate Fay-Herriot models produce a more efficient parameter estimation than direct estimation and univariate model.

Introduction

Survey sampling is a data collection method by observing several units of observation to obtain information from the entire population. Compared to other data collection methods, survey sampling has advantages in cost, time, and human resources. Survey sampling is designed for certain size of domain, commonly a large area. However, data demand for small areas is increasing and becomes high issues (Ghosh and Rao, 1994). The inadequate sample size causes a large standard error of parameter estimates. This problem is overcome by indirect estimation, namely Small Area Estimation (SAE).

Rao and Molina (2015) said that SAE increases the effectiveness of sample size using the strength of neighboring areas and information on other variables that are related to the variable of interest. There are some estimation methods in SAE, namely Best Linear Unbiased Predictors (BLUP), Empirical Best Linear Unbiased Predictors (EBLUP), Hierarchial Bayes (HB), and Empirical Bayes (EB). The most common SAE estimator is the EBLUP (Krieg et al., 2015). EBLUP has advantages over EB and HB method. It is a development of BLUP method that minimizes the MSE among other unbiased linear estimators (Ghosh and Rao, 1994). Area level of EBLUP application for continuous response variable, called Fay Herriot Model, was firstly employed for estimating log per-capita income (PCI) in small places in the US (Rao and Molina, 2015).

The Fay-Herriot model has extended into a multivariate Fay-Herriot model, which is a model with several correlated response variables. Datta et al. (1991) firstly applied the multivariate model to estimate the median income of four person families in the US states. Benavent and Morales (2016) developed multivariate Fay-Herriot models with EBLUP method and introduced four estimation models based on the estimated variance matrix structure. Ubaidillah et al. (2019) also implemented multivariate Fay-Herriot model and indicated that multivariate Fay-Herriot model produces a more efficient parameter estimation than the univariate model.

On the Comprehensive R Archive Network (CRAN), there are several packages implementing small area estimation. Some of them are included in the Small Area Estimation subsection of The CRAN Task View: Official Statistics & Survey Methodology (Templ, 2014), including: sae (Molina and Marhuenda, 2018), rsae (Schoch, 2014), nlme (Pinheiro et al., 2020), hbsae (Boonstra, 2012), JoSAE (Breidenbach, 2018), and BayesSAE (Chengchun Shi Developer, 2018). Other popular SAE packages not included in that subsection are mme (Lopez-Vizcaino et al., 2019) and saery (Lefler et al., 2014).

In this paper, we introduce our R package of multivariate Fay-Herriot models for small area estimation, named msa. This package and its details are available on CRAN at http://CRAN.R-project.org/package=msae. Functions in this package implement four Fay-Herriot Models, namely Model 0, Model 1, Model 2, and Model 3 as proposed by Benavent and Morales (2016).

The paper is structured as follows. First, we explain multivariate Fay-Herriot models in the Section 2.2. Then, we describe msa package and illustrate the use of this package for SAE estimation by employing simulation studies and applying to a real dataset in the next Sections 2.3 and 2.4. Finally, we provide a conclusion in the in Section 2.8.

Multivariate Fay-Herriot model

Multivariate Fay-Herriot model is an extension of Fay-Herriot model which utilizes some correlated responses. Fay-Herriot is combination of two model components. The first component is called sampling model, and the second component is called linking model.
Suppose we want to estimate characteristics of $R$ variables in $D$ areas, $\mu_d = (\mu_d1, \ldots, \mu_dR)^T$, with $d = 1, \ldots, D$. Let $y_d = (y_{d1}, \ldots, y_{dR})^T$, be a direct estimator of $\mu_d$. The first component i.e. sampling model is

$$y_d = \mu_d + e_d, \quad e_d \sim N(0, V_{ed}), \quad d = 1, \ldots, D$$

where $e_d$ is sampling error with covariance matrix, $V_{ed}$, that assumed to be known. In the second component, we assume that $\mu_d$ is linearly related with $p_d$ area specific auxiliary variables $X_d = (X_{d1}, \ldots, X_{dp})^T$ as follows:

$$\mu_d = X_d\beta_d + u_d, \quad u_d \sim N(0, V_{ud}), \quad d = 1, \ldots, D$$

where $u_d$ is area random effects and $\beta_d$ is a vector of regression coefficient corresponding with $X_d$. This second component is called linking model. The combination of the two components forms a multivariate linear mixed model as follows:

$$y_d = X_d\beta_d + u_d + e_d, \quad e_d \sim N(0, V_{ed}), \quad d = 1, \ldots, D$$

where $u$ and $e$ are independent.

Benavent and Morales (2016) proposed Fay-Herriot Models using four different variance matrices, called Model 0, Model 1, Model 2, and Model 3. Model 0 is an univariate Fay-Herriot Model, of which the sampling error and the random effect of target variables are independent. Sampling error and random effect variance matrix is written as follows:

$$V_{ud} = \text{diag}_{a \leq r \leq R}(\sigma^2_{dr})$$

$$V_{ed} = \text{diag}_{a \leq r \leq R}(\sigma^2_{edr})$$

where $d = 1, \ldots, D$

Model 1, Model 2, and Model 3 are multivariate Fay-Herriot models, of which the variance matrices are no longer diagonal matrices. Model 1 is a multivariate form of Model 0, where the random effect variance of Model 1 is still a diagonal matrix. Model 2 is called autoregressive multivariate Fay-Herriot model (AR(1)), which the random variance matrix are written as follows:

$$V_d = \sigma^2_{edr} \Omega_d(p)$$

$$\Omega_d(p) = \frac{1}{1 - p^2} \begin{bmatrix} 1 & p & \cdots & p^{R-1} \\
p & 1 & \cdots & p^{R-2} \\
\vdots & \vdots & \ddots & \vdots \\
p^{R-1} & p^{R-2} & \cdots & 1 \end{bmatrix}$$

Model 3 is called heteroskedastic autoregressive multivariate Fay-Herriot model (HAR(1)), which the element of random error is written as follows:

$$u_{dr} = \rho u_{d,r-1} + a_{dr}$$

$$u_{d0} \sim N(0, \sigma^2_{d0}) \quad \text{and} \quad a_{dr} \sim N(0, \sigma^2_{dr})$$

where $\sigma^2_{d0} = 1, a_{dr},$ and $u_{d0}$ are independent. The element of random variance matrix is written as follow:

$$\sigma^2_{drij} = \sum_{k=1}^i \rho^{2k} \sigma^2_{i-k}$$

$$\sigma^2_{drij} = \sum_{k=0}^{\|i-j\|} \rho^{2k+\|i-j\|} \sigma^2_{i-j-k}$$

**BLUP and EBLUP**

The best linear unbiased prediction (BLUP) of $\mu$ is

$$\hat{\mu} = X\hat{\beta} + Z^T \hat{V}_d Z \Omega^{-1} (y - X\hat{\beta})$$

where $\hat{\beta} = (X^T \Omega^{-1} X)^{-1} X^T \Omega^{-1} y$ is the best linear unbiased estimator (BLUE) of $\beta$ with the covariance matrix $\text{cov}(\hat{\beta}) = (X^T \Omega^{-1} X)^{-1}$. BLUP estimator depends on the random effect variance that is usually unknown. Using Restricted Maximum Likelihood (REML), we estimate and substitute random effect variance estimator to obtain the multivariate EBLUP estimator. The estimation formula with EBLUP is
written as follows:
\[
\hat{\mu} = X\hat{\beta} + Z^TV_uZ\hat{\Omega}^{-1}(y - X\hat{\beta})
\]
\[
\hat{\Omega} = Z^TV_uZ + V_e
\]
where \( \hat{\beta} = (X^T\hat{\Omega}^{-1}X)^{-1}X^T\hat{\Omega}^{-1}y \) is the best linear unbiased estimator (BLUE) of \( \beta \) with the covariance matrix \( \text{cov}(\hat{\beta}) = (X^T\hat{\Omega}^{-1}X)^{-1} \).

**MSE**

Benavent and Morales (2016) also proposed MSE estimation for multivariate Fay-Herriot models as follows:

\[
\text{mse}(\hat{\mu}) = g_1(\hat{\sigma}_u^2) + g_2(\hat{\sigma}_u^2) + g_3(\hat{\sigma}_u^2)
\]

where each component can be described as follows:

\[
g_1(\hat{\sigma}_u^2) = \Gamma V_e
\]
\[
g_2(\hat{\sigma}_u^2) = (1 - \Gamma)X(X^T\hat{\Omega}^{-1}X)^{-1}X^T(I - \Gamma)^T
\]
\[
g_3(\hat{\sigma}_u^2) \approx \Sigma \Sigma \text{cov}(\hat{\sigma}_{uk}^2, \hat{\sigma}_{ul}^2) \Gamma(k_{(k)} \Omega^{T(k)_l}) \Gamma \delta, \delta = 1, 2, \ldots, q
\]

where \( \Gamma = Z^TV_uZ, \Gamma_{(k)} = \frac{\delta^T}{\delta^2 \sigma_u^2} \), and \( \text{cov}(\hat{\sigma}_{uk}^2, \hat{\sigma}_{ul}^2) \) is the inverse of the Fisher information matrix in the estimation of REML.

**Overview of R package msae**

The R Package `msae` implements multivariate Fay-Herriot models for small area estimation. Here are some functions and the descriptions at a glance:

- `eblupUFH`: This function gives the EBLUP and MSE based on Univariate Fay-Herriot Model (Model 0).
- `eblupMFH1`: This function gives the EBLUP and MSE based on Multivariate Fay-Herriot Model (Model 1).
- `eblupMFH2`: This function gives the EBLUP and MSE based on Autoregressive Multivariate Fay-Herriot Model (Model 2).
- `eblupMFH3`: This function gives the EBLUP and MSE based on Heteroskedastic Autoregressive Multivariate Fay-Herriot Model (Model 3).

Those functions return a list of five elements:

- `eblup` is a dataframe of EBLUPs for each variable.
- `MSE` is a dataframe of estimated MSEs of the EBLUPs.
- `randomEffect` is a dataframe of random effect estimators.
- `Rmatrix` is a block diagonal matrix composed of sampling variances.
- `fit` is a list containing following objects:
  - `method` shows type of fitting method.
  - `convergence` shows convergence of Fisher Scoring algorithm.
  - `estcoef` shows estimated model coefficients and their significance.
  - `refvar` shows the estimated random effect variance.
  - `refvarTest` (only for `eblupMFH3`) shows homogeneity of random effect variance test based on Model 3.
  - `rho` (only for `eblupMFH2` and `eblupMFH3`) shows the estimated \( \rho \) of random effect variance and their parameter test.
  - `informationFisher` is a matrix of information Fisher.

This package also provides datasets generated for each multivariate models. The datasets are generated based on Model 1, Model 2, and Model 3 following below steps:

1. Generate sampling error \( e \) and auxiliary variables « \( X_1, X_2 \) ». Set the parameter as follows:
The R Journal Vol. XX/YY, AAAA 20ZZ

Example 1. Multivariate Fay-Herriot model (Model 1)

datasae1, which is generated based on Model 1, contains 50 observations on the following 11 variables: 3 dependent variables « Y1, Y2, and Y3 », 2 auxiliary variables « X1 and X2 », and 6 variance-covariance of direct estimation « v1, v2, v3, v12, v13, and v23 ». The procedures for generating such datasets are provided in the previous section. The following R commands are run to obtain EBLUPs of univariate Fay-Herriot model (Model 0) and multivariate Fay-Herriot model (Model 1), to plot the EBLUPs of univariate and multivariate model, and also to plot the MSEs of EBLUPs in univariate and multivariate model:

data('datasae1')

# model specifications
Fo <- list(f1=Y1~X1+X2,
f2=Y2~X1+X2,
f3=Y3~X1+X2)
vardir <- c("v1", "v2", "v3", "v12", "v13", "v23")

# EBLUP based on Model 0 and Model 1
u <- eblupUFH(Fo, vardir, data=datasae1) # Model 0
m1 <- eblupMFH1(Fo, vardir, data=datasae1) # Model 1

# Figure 1: EBLUPs under Model 0 and Model 1
par(mfrow=c(1,3))

plot(u$eblup$Y1, type = "o", col = "blue", pch = 15, xlab = "area", ylab = "Y1",
cex.axis = 1.5, cex.lab = 1.5, xaxt = "n")
points(m1$eblup$Y1, type = "o", col = "red", pch = 18)
axis(1, at=1:50, labels = 1:50)
legend("topleft",legend=c("Model 0","Model 1"),ncol=2 , col=c("blue","red"),
pch=c(15,18), inset=c(0.617,-0.1), xpd=TRUE)

plot(u$eblup$Y2, type = "o", col = "blue", pch = 15, xlab = "area", ylab = "Y2",
cex.axis = 1.5, cex.lab = 1.5, xaxt = "n")
points(m1$eblup$Y2, type = "o", col = "red", pch = 18)
axis(1, at=1:50, labels = 1:50)
legend("topleft",legend=c("Model 0","Model 1"),ncol=2 , col=c("blue","red"),
pch=c(15,18), inset=c(0.617,-0.1), xpd=TRUE)

plot(u$eblup$Y3, type = "o", col = "blue", pch = 15, xlab = "area", ylab = "Y3",
cex.axis = 1.5, cex.lab = 1.5, xaxt = "n")
points(m1$eblup$Y3, type = "o", col = "red", pch = 18)
axis(1, at=1:50, labels = 1:50)
legend("topleft",legend=c("Model 0","Model 1"),ncol=2 , col=c("blue","red"),

The R Journal Vol. XX/YY, AAAA 20ZZ

ISSN 2073-4859
Figure 1 illustrates the EBLUPs based on Model 0 (univariate model) and Model 1 (multivariate model) for all variables of interest. Figure 2 shows the MSEs of Model 1 compared with the MSEs of Model 0. It can be seen that the estimates of both methods show a similar pattern. Meanwhile, EBLUPs based on Model 1 has a lower MSE than the Model 0. From this example, we can conclude that multivariate Fay-Herriot model (Model 1) is more efficient than univariate Fay-Herriot model (Model 0).
Example 2. Autoregressive multivariate Fay-Herriot model (Model 2)

data2, which generated based on Model 2, contains 50 observations on the following 11 variables: 3 dependent variables \(Y_1, Y_2\) and \(Y_3\), 2 auxiliary variables \(X_1\) and \(X_2\), and 6 variance-covariance of direct estimation \(v_1, v_2, v_3, v_{12}, v_{13},\) and \(v_{23}\). We compare the effectiveness of univariate model (Model 0) and autoregressive multivariate Fay-Herriot Model (Model 2) by their MSE. We use \texttt{eblupMFH2()} to estimate parameters based on Model 2. Then, we plot the EBLUP and MSE of these methods to compare them.

data('data2')

# model specifications
Fo <- list(f1=Y1~X1+X2, f2=Y2~X1+X2, f3=Y3~X1+X2)
vardir <- c("v1", "v2", "v3", "v12", "v13", "v23")

# EBLUP based on Model 0 and Model 2
u <- eblupUFH(Fo, vardir, data=data2) # Model 0
m2 <- eblupMFH2(Fo, vardir, data=data2) # Model 2

The the EBLUPs based on Model 0 (univariate model) and Model 1 (autoregressive multivariate model) are shown in Figure 3. As it can be seen, both method show an almost similar result. However, EBLUPs based on Model 2 has a lower MSE than the EBLUPs based on Model 0 as shown in Figure 4. In this example, autoregressive multivariate Fay-Herriot model (Model 2) seems to be more efficient than univariate Fay-Herriot model (Model 0).

![Figure 3: EBLUPs under Model 0 and Model 2.](image1)

![Figure 4: MSE of EBLUPs under Model 0 and Model 2.](image2)

Example 3. Heteroskedastic autoregressive multivariate Fay-Herriot model (Model 3)

data3, which generated based on Model 3, is structured the same as data1 and data2. We compare the effectiveness of univariate model (Model 0) and heteroskedastic autoregressive
multivariate Fay-Herriot Model (Model 3) by their MSE. We use eblupMFH3() to estimate parameters based on Model 3. Then, we plot the EBLUP and MSE of these method to compare them.

data('datosae3')

# model specifications
Fo <- list(f1=Y1~X1+X2,
          f2=Y2~X1+X2,
          f3=Y3~X1+X2)
vardir <- c("v1", "v2", "v3", "v12", "v13", "v23")

# EBLUP based on Model 0 and Model 3
u <- eblupUFH(Fo, vardir, data=datosae3) # Model 0
m3 <- eblupMFH3(Fo, vardir, data=datosae3) # Model 3

Figure 5 shows EBLUPs based on Model 3 compared to the Model 0. Whereas, the MSEs of both methods is shown in Figure 6. It can be seen that the multivariate EBLUPs will follow the pattern of univariate EBLUPs with smaller MSE values. It can be concluded that the heteroskedastic autoregressive multivariate Fay-Herriot model (Model 3) is more efficient than univariate model (Model 0).

Real data example: Poverty index

In this section, we use incomedata dataset, which is provided in library sae. The dataset contains unit-level data on income and other related variables in Spain. We will demonstrate how to estimate EBLUP of Foster-Greer-Thorbecke (FGT) poverty index for each province using Multivariate Fay-Herriot Models. The index consists of three indicators, i.e. poverty proportion (p0), poverty gap (p1), and poverty severity (p2).

library(sae)
data("incomedata")
Firstly, we obtain area-level data by calculating poverty indicators for each unit and aggregating it by province based on Benavent and Morales (2016). We use poverty line $z=6557.143$ (Molina and Marhuenda, 2015). These following R commands are run to obtain $p_0$, $p_1$, and $p_2$ as variables of interest.

```r
library(tidyverse)

pov.line <- rep(6557.143, dim(incomedata)[1]) # poverty line

# calculate unit indicators
incomedata$y <- (pov.line - incomedata$income)/pov.line
incomedata = incomedata %>% mutate(poverty = ifelse(incomedata$y > 0, TRUE, FALSE),
                                 y0 = ifelse(incomedata$y > 0, incomedata$y^0, 0),
                                 y1 = ifelse(incomedata$y > 0, incomedata$y^1, 0),
                                 y2 = ifelse(incomedata$y > 0, incomedata$y^2, 0))

# estimated domain size
est.Nd <- aggregate(incomedata$weight, list(incomedata$prov), sum)[,2]

## estimate P0 P1 dan P2
prov.est = incomedata %>% group_by(prov) %>%
  summarise(p0.prov = sum(weight*y0),
            p1.prov = sum(weight*y1),
            p2.prov = sum(weight*y2)) %>%
  mutate(p0.prov = p0.prov / est.Nd,
         p1.prov = p1.prov / est.Nd,
         p2.prov = p2.prov / est.Nd)

incomedata <- incomedata %>% left_join(prov.est, by = c("prov" = "prov"))
```

We also need variance and covariance of variables of interest to estimate using multivariate Fay-Herriot model. The following R commands are run to obtain variance and covariance of direct estimation based on Benavent and Morales (2016).

```r
# estimate direct estimation variance-covariance
prov.variance = incomedata %>%
  mutate(v11 = ifelse(incomedata$poverty,
                      (weight*(weight-1))*(y0-p0.prov)*(y0-p0.prov), 0),
         v12 = ifelse(incomedata$poverty,
                      (weight*(weight-1))*(y0-p0.prov)*(y1-p1.prov), 0),
         v13 = ifelse(incomedata$poverty,
                      (weight*(weight-1))*(y0-p0.prov)*(y2-p2.prov), 0),
         v22 = ifelse(incomedata$poverty,
                      (weight*(weight-1))*(y1-p1.prov)*(y1-p1.prov), 0),
         v23 = ifelse(incomedata$poverty,
                      (weight*(weight-1))*(y1-p1.prov)*(y2-p2.prov), 0),
         v33 = ifelse(incomedata$poverty,
                      (weight*(weight-1))*(y2-p2.prov)*(y2-p2.prov), 0)) %>%
  group_by(prov) %>%
  summarise_at(c("v11","v12","v13","v22","v23","v33"), sum) %>%
  mutate_at(c("v11","v12","v13","v22","v23","v33"),
            function(x){x/est.Nd^2})
```

We use six explanatory variables selected by stepwise method, i.e. indicator of age group 50-64 (age4), indicator of age group $\geq 65$ (age5), indicator of education level 1 (educ1), indicator of education level 2 (educ2), indicator of education level 3 (educ3), and indicator if Spanish nationality (nat1). The model specifications are written as follow:

```r
formula <- list(f1=p0.prov~age4+age5+educ1+educ2+educ3+nat1,
                f2=p1.prov~age4+age5+educ1+educ2+educ3+nat1,
                f3=p2.prov~age4+age5+educ1+educ2+educ3+nat1)
vardir <- c("v11", "v22", "v33", "v12", "v23", "v13")
```

Next, we select the most suitable multivariate Fay-Herriot model using variance homogeneity test and random effect $\rho$ parameter test. In the variance homogeneity test, we test $H_0: \sigma^2_{ui} = \sigma^2_{uj}$; $i, j = 1, 2, 3$ using model 3. We obtain a non-convergent model, the $p-values$ are 0.98674 and 0.98996.
shows that the difference between variance of random effects are statistically not significant. After that, we test $H_0: \rho = 0$ using model 2. We get the $t$ - statistics value of 19.26 with $p$ - value of 0.00. It shows that there is correlation between random effects. These results indicate the model that fits the data is Model 2.

The following codes are run to obtains the EBLUPs (under Model 2), to plot the direct estimates and the EBLUPs, and to plot the MSES of direct estimates and the MSES of EBLUPs ordered by sample size:

```r
# EBLUP based on Model 2
eblup.pov <- eblupMFH2(formula, vardir, data=prov.data)

# Dataframe of Result
result_eblup = data.frame(prov = prov.data$prov,
est.Nd = est.Nd,
p0 = prov.data$p0.prov, p0.eblup = eblup.pov$eblup$p0.prov,
p1 = prov.data$p1.prov, p1.eblup = eblup.pov$eblup$p1.prov,
p2 = prov.data$p2.prov, p2.eblup = eblup.pov$eblup$p2.prov,
v11 = prov.data$v11, p0.mse = eblup.pov$MSE$p0.prov,
v22 = prov.data$v22, p1.mse = eblup.pov$MSE$p1.prov,
v33 = prov.data$v33, p2.mse = eblup.pov$MSE$p2.prov)
result_eblup = result_eblup %>% arrange(est.Nd)
result_eblup$prov = as.factor(result_eblup$prov)

We will compare EBLUPs based on Model 2 with the direct estimates. Both of the estimation results can be seen in Table 1. On the median value, result of estimated poverty indicators are relatively

Table 1: Statistics of direct estimation and Model 2

similar, ranging from 0.218-0.219 for p0, 0.0681-0.0687 for p1, and 0.0323-0.0336 for p2. Model 2 has a lower range and smaller standard deviation than the direct estimation. It means that in general, multivariate Fay-Herriot model has lower variability of small area estimates than direct estimation.

![Figure 7: Direct estimates and EBLUPs (under Model 2) of p0, p1, and p2 ordered by sample size.](image)

The result of direct estimates and EBLUPs under Model 2 ordered by sample size are shown in Figure 7. The pattern of small area estimates for both methods are almost the same for all area. The MSE of the direct estimates and the EBLUP estimates ordered by sample size are shown in Figure 8. These plots show that multivariate Fay-Herriot model has lower MSE than the direct estimation. Thus, we can conclude that multivariate Fay-Herriot model is more efficient than direct estimation.

**Conclusion**

This paper introduces the first R package of multivariate Fay-Herriot model for small area estimation named msa. The package is available on Comprehensive R Archive Network (CRAN) at [http://CRAN.R-project.org/package=msae](http://CRAN.R-project.org/package=msae). This package contains a number of functions for estimating the EBLUP and MSE of EBLUP of each Fay-Herriot Model. This package accomodates univariate Fay-Herriot model (model 0), multivariate Fay-Herriot model (model 1), autoregressive multivariate Fay-Herriot model (model 2), and heteroskedastic autoregressive multivariate Fay-Herriot model (model 3). The functions are decribed and implemented using three examples of datasets provided.
in \texttt{msae} package and a real dataset provided in \texttt{sae} package, \texttt{incomedata}. By these examples, we show that multivariate Fay-harryiot models produce more efficient parameter estimates than direct estimation and univariate model.
